

Nexus Document Platform 4.2 — Metadata Processing

Pipeline

Metadata processing consists of normalization, file inspection, metadata extraction, validation, enrichment, and persistence.

Normalization

File names are normalized to Unicode NFC. Empty fields are removed. Dates are converted to UTC where the source format is unambiguous.

Extraction

PDF documents use the PDF extractor. Office documents use format-specific extractors. Images can use OCR when `OCR_ENABLED` is true. Code files use language-aware parsers.

Validation

Required metadata includes `document_id`, `content_type`, `source_name`, and `extracted_at`. Invalid records are rejected before persistence.

Retries

Transient storage and database errors are retryable. Unsupported file formats are not retryable. Malformed documents are moved to the quarantine workflow.
